Containerization

Containers have reshaped the way companies think about developing, deploying, and maintaining applications. A container consists of an entire runtime environment — an application, plus all its dependencies, libraries and other binaries, and configuration files needed to run it — bundled into one package. Containers isolate software from its environment, enabling applications to run quickly and reliably from one computing environment to another.

Much like virtualization via virtual machines (VMs) and hypervisors, containers were created to improve data center efficiency and the speed and agility of application development. In addition to increasing hardware efficiency by supporting multiple users and applications in parallel, containerization also:

- Makes it quick and easy to deploy applications and databases consistently across multiple environments because the core operating system (OS) can be configured independently from the application container.
- Improves productivity by simplifying application portability, making it possible for IT operations teams to build and run applications and databases anywhere there is a compatible OS or control plane — on-premises and in the cloud.
- Enables developers to create predictable environments that are isolated from other applications, so that they, and IT Operations teams, spend less time debugging and diagnosing differences in environments, and more time building new applications and competitive business services.
- Provides developers with a sandboxed view of the OS, logically isolated from other applications. This reduces the number of fixes post release because developers know that what is built in development and test environments will hold true in production.

You will find little argument among developers as to the value of using containers for test and development of applications. As outlined above, speed, efficiency and portability are what agile development and Dev/Ops strategies embody. However, container adoption for databases, such as Microsoft® SQL Server®, has been hindered by two factors:

1. Lack of support for persistent storage of database files separate from ephemeral container files.
2. Concerns over compatibility with infrastructure components and software.

“Gartner predicts that by 2022, more than 75% of global organizations will be running containerized applications in production...”¹

Microsoft SQL Server on containers

As organizations embrace digital transformation, they are looking for technologies that drive innovation across their entire organization. Containers can help enterprises modernize legacy applications and create new cloud-native applications that are both scalable and agile in this new digital era. As a result, there has been an increase the adoption of containers.

Digital transformation has also been a driving force for evolving relational databases into the next generation of data management platforms capable of supporting advanced business intelligent applications, artificial intelligence (AI) and machine learning (ML) applications, and more agile application development platforms.

In response, Microsoft has been expanding its software offerings to include support for a broader range of operating systems, including Red Hat Enterprise Linux (RHEL) and SUSE Linux Enterprise Server, and programming languages, R and

Python. This has paved the way for Microsoft to offer SQL Server on Docker containers — the world’s leading containerization platform² tool for building, distributing, and running containers and runs natively on Linux.

Microsoft first introduced SQL Server containers on Linux with the release SQL Server 2017 and is expanding these capabilities with SQL Server 2019. SQL Server 2019 Microsoft will make it even easier to adopt SQL Server in containers by enabling new high availability (HA) scenarios; Linux-based container images on Microsoft Container Registry; Red Hat-Certified Container [Images](#); and the SQL Server operator for Kubernetes, which makes it easy to deploy an Availability Group.

Containerized Databases: Test, Development and Production

Containers are designed to be “short-lived” — or stateless — by nature which is why many organizations use containers for test and development purposes. Application developers most often work outside of the server environments their programs need to run in. To minimize conflicts in library versions, dependencies and configuration settings, the production environment needs to be recreated multiple times for development, testing and pre-production integration. However, when it comes to building or updating databases, like SQL Server, the data needs to be persistent and must survive through the restart or re-scheduling or deletion of a container. When containers are rescheduled the storage should also be shifted and made available on a new host, for the container to start without incident.

Containers can also be valuable for production SQL Server database environments. When it comes to production environments, high availability and disaster recovery are of great concern. The inability of applications to access data, or worse, loss of critical business data has far reaching financial and legal impacts. The idea of using an ephemeral container environment may not appear to be wise business decision. However, data platforms, such as Microsoft’s SQL Server, have evolved to provide the ability to achieve the benefits of database containerization in production environments. Microsoft SQL Server 2019 provides the enterprise-class HA and disaster recovery capabilities needed for production deployments, with containers orchestrated by Kubernetes and [Always On Availability Groups](#). Companies can configure a SQL Server instance on Kubernetes with persistent storage for high availability. If the SQL Server instance fails, Kubernetes automatically re-creates it in a new pod — providing resiliency against a node failure. Also, Kubernetes orchestrates instances of SQL Server in container images that participate in a SQL Server Always On Availability Group providing improved health monitoring, faster recovery, rolling upgrades, offload backup, and read scale out. SQL Server container with Availability Groups, provides the enterprise-class high availability and disaster recovery capabilities need for production deployments.

Dell EMC CSI plugins: Integration for better orchestration, automation and management of container storage

Container engines such as Docker and orchestration frameworks such as Kubernetes, provide a standardized way to package applications — including the code, runtime and libraries — and to run them in a consistent manner across the entire software development life cycle. The CSI is a standard for exposing arbitrary block and file storage systems to containerized workloads on Container Orchestration Systems (COs) like Kubernetes.

To effectively address the challenges of stateless containers and the need for persistent storage, Dell EMC storage solutions provide

unique CSI Plugins which allow customers to deliver persistent storage for container-based applications for both development and production scale. The combination of the Kubernetes orchestration system and Dell EMC storage CSI plugins enables simplified provisioning of containers and persistent storage.

Dell EMC recently [tested and validated a solution](#) using Microsoft SQL Server 2019 containers for an application development and testing environment hosted on a Dell EMC platform. Kubernetes enhanced with the XtremIO X2 CSI plugin provided the capability to attach and manage all-flash XtremIO X2 volumes to containerized applications. This solution demonstrated how developers can leverage a familiar Kubernetes experience to create a copy of the SQL database and connect it to the SQL Server container. Developers can then modify the database and protect progress by using XtremIO Virtual Copies (snapshots) to save a copy of the database.

The integration capabilities of Dell EMC storage CSI plugins also make it possible for developers, database administrators, and storage administrators to utilize interfaces they are most comfortable with — such as command line interface (CLI), the Kubernetes dashboard, and, in this example, the XtremIO X2 user interface (UI) — to provision and manage persistent storage. A developer can provision storage without having to make requests to the storage administrator, making storage available in seconds vs. hours as seen with traditional and manual processes, while the storage administrator is still able to monitor the newly added storage resources.

Microsoft and Dell EMC – making database containerization a reality

Whether customers are looking to use containers for test and development purposes, like DevOps, or to deploy databases with container orchestrators such as Kubernetes, SQL Server in containers ensures a consistent, isolated and reliable behavior across environments, that is easy to use, start and stop. Customized content can be built on top of SQL Server containers, and run without being affected by the rest of the environment. This isolation makes SQL Server in containers ideal for test deployment scenarios as well as DevOps processes.

Dell EMC brings the power of persistent storage to a stateless platform. Dell EMC's storage and CSI plugins enable container orchestrators, like Kubernetes, to easily provision highly available and scalable container volumes for stateful containerized applications and databases.

IT professionals and application developers can leverage the advantages of Docker, Kubernetes, Microsoft SQL Server and Dell EMC storage, servers and network to improve the efficiency of the test and development process and shorten the time to value of new application development.
