Bare Metal Orchestrator

Bare Metal Orchestrator: The easy way to manage hardware

Automate and orchestrate a fleet of hundreds of thousands of bare-metal devices to workload readiness with one simple solution

The virtualization and, increasingly, the cloudification of telecommunication networks are a response to changing market economics and opportunities. On the one hand, communication service providers (CSPs) need to run their networks more efficiently, even as they scale out those networks to meet increased demands for data, video, and rich-media services. On the other hand, new services such as those being promised by 5G will require CSPs to run their business with agility, flexibility, and openness to innovation. Moving to virtual and cloud-native network functions (VNFs/CNFs) allows CSPs to both reduce costs and improve business agility for the future.

The upside to a virtualized, cloud-native network infrastructure is the flexibility it brings by combining best-in-class software and hardware from multiple vendors. In essence, CSPs are no longer locked into a single vendor’s vision of the future, but can bring together high-performance servers, switches, advanced software, and composable cloud solutions from industry leaders to build the best network for their business. Yet there is a potential downside to this model too, in the form of added management complexity. Specifically, managing thousands or even tens of thousands of servers and switches in distributed locations can be daunting, time-consuming, and prone to human error.

Infrastructure automation offers a solution to the challenge of managing a massive, disaggregated, virtualized network. Dell Technologies’ Bare Metal Orchestrator provides powerful automation tools in a single, simple solution that is designed to help CSPs manage hundreds of thousands of computing and networking nodes across core, edge, and RAN environments in any geographic location.

Figure 1. A graphical, intuitive interface makes it simple to identify and manage infrastructure by site location
One solution manages the entire lifecycle for computing and networking nodes

For years, CSPs have embraced virtualization in the core network in order to accelerate service creation and deliver better service experiences to their customers. More recently, virtualization has moved to the network edge and the Radio Access Network (RAN). Virtualized RAN (vRAN) solutions are particularly attractive because of the deployment flexibility they offer and the substantial cost savings that can be achieved by disaggregating RAN functions (e.g., the centralized unit, distribution unit, and radio unit) through VNFs/CNFs and commercial off-the-shelf (COTS) servers.

Dell Technologies’ Bare Metal Orchestrator enables CSPs to manage all their bare metal servers and switches today—up to hundreds of thousands of devices—through a single consolidated and centralized view that shows all hardware infrastructure at-a-glance. Dell Technologies plans to extend these lifecycle management capabilities storage nodes as well, providing a complete end-to-end infrastructure management framework. This greatly simplifies the task of managing the lifecycle of hardware in a dynamic, disaggregated network by allowing network teams to easily discover, deploy, and update hardware anywhere. Instead of manual configurations and regional management teams, CSPs can remotely and centrally manage every server in their network with Bare Metal Orchestrator using standards-based Redfish APIs for maximum efficiency, resiliency, and agility across multivendor networks.

Figure 2. Inventory of all devices at a specific location for better management capabilities
Focus on outcomes, let automation do the rest

Bare Metal Orchestrator uses declarative automation, which means that CSPs only need to define the desired outcome of their infrastructure environment and Bare Metal Orchestrator does the rest, determining which commands will achieve those desired states based on workload requirements and current network service demands. Declarative automation allows CSPs to get the best results from their network without requiring highly specialized domain expertise to program and configure their hardware. The ability to consistently test, validate, and deploy telecom infrastructure greatly reduces the risk and accelerates the time to market for new services.

With declarative automation, CSPs declare their virtual infrastructure deployment as an outcome. Bare Metal Orchestrator then translates that outcome into the steps needed to compose and deploy all necessary elements of the stack. This includes:

- Boot-strapping the compute with BIOS configurations, firmware, and host OS/hypervisor
- Boot-strapping network devices, upgrading NOS, and configuring VLANs across multi-vendor environment
- Connecting the hosts via the selected network topology
- Deploying the VIM into a workload-ready state

Bare Metal Orchestrator is the right software for hardware

Managing thousands of hardware devices is challenging... but it can be much easier with Bare Metal Orchestrator:

- Quickly deploy and manage thousands of servers and switches anywhere in your network using open, industry-standard Redfish APIs
- Eliminate hardware configuration errors with simple, declarative automation tools
- Declaratively deploy workload-ready, virtualized infrastructure stacks
- Collect rich network insights in one place and use those insights to create new services and improve customer experiences
Monitoring and health

Dell Technologies’ Bare Metal Orchestrator has a dashboard that can be used to quickly identify the health of your infrastructure to improve network performance, plan network capacity, and identify new service opportunities for the future. With Bare Metal Orchestrator, CSPs can manage the network of tomorrow with the skills and resources they have today using simple, intuitive, unified automation controls that ensure every single server is working hard in their network.

Figure 3. A graphical intuitive interface makes it simple to manage individual servers and more

Bare Metal Orchestrator feature summary:

Scope
- Open architecture
- Redfish multi-vendor support
- Compute and network devices
- Multi-tenant and multi-vendor
- Environmental awareness

Metering and Chargeback
- Usage based billing

Automation
- Auto-Discovery

Inventory reconciliation
- Zero touch deployment
- Provisioning
- Upgrade
- Config personality management
- VIM/Stack deployment

Hardware Management
- Firmware management
- Health and utilization
- Out of band management
Security
- Certificate Management
- Secure data erasure

Self Service
- Common portal

Composability
- By location, workload, platform

Programmability
- Declarative automation
- API first strategies
- Infrastructure as code

Federation
- Entire fleet under one umbrella
- User interface
- Single API entry point

Scale
- Tens of thousands of sites
- Globally distributed
- Single node to multi-rack

Multi-vendor support
- Dell, HPE, and Supermicro servers
- Dell and Cisco networking

Log management
- Detailed logging
- Event monitoring Back-up / Restore
- Configuration
- Firmware back-up and rollback
